Personal Projects

HuertaDirecta – Software for Agricultural Product Management and Sales

HuertaDirecta is software developed as a personal project, focused on the management and sale of agricultural products.

It implements role-based access control, secure authentication, user management, order management, and delivery services, as well as administrative and customer support modules. The project is designed following software development best practices, using a layered MVC architecture with a focus on scalability and maintainability.

Because apparently even vegetables need enterprise-grade architecture now. Somewhere a tomato is being authenticated through JWT.

Technology Stack

- Backend developed in Java using Spring Boot, with a layered architecture (controllers, services, and repositories).
- PostgreSQL as the relational database.
- Frontend based on HTML5, CSS3, Bootstrap, Tailwind CSS, React 19.2, and Thymeleaf.
- REST API integration for communication between frontend and backend.
